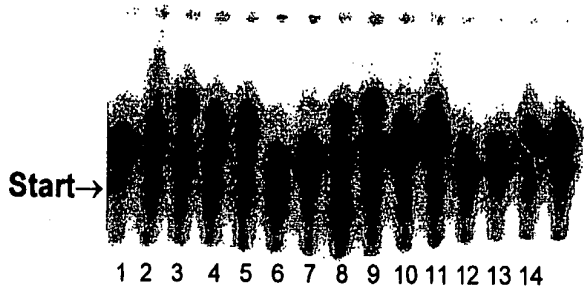
(54) Title: NUCLEOSIDE DERIVATIVES FOR LIBRARY PREPARATION



(57) Abstract: Nucleoside derivatives as building blocks for templated libraries are described.

WO 02/102820 A1

Nucleoside derivatives for Library Preparation

Technical Field of the Invention

The present invention relates to nucleotide derivatives. The nucleotide derivatives of the present invention are useful in the preparation of templated molecules.

Background

The generation of molecules carrying new properties remains a challenging task. Recently, a number of procedures have been suggested that should allow a more efficient generation and screening of a larger number of molecules. The approaches taken involve the encoding and/or templating of molecules other than natural biopolymers such as peptide, RNA and DNA. These approaches allow the researcher to generate and screen a huge number of molecules in a short time. This should lead to better molecules carrying the desired properties.

The central dogma of biology describes the one-way flow of information from DNA to RNA to protein. Recently, methods such as phage display, peptides-on-plasmids, ribosome display and mRNA-protein fusion have been developed, allowing the transfer of information from the level of protein/peptide to RNA or DNA. This has enabled the use of molecular evolution to be applied on huge numbers of peptides that are exposed to an enrichment process, where after the enriched pool of molecules (enriched for a particular feature, such as binding to receptor protein) are amplified, by exploiting information flow from the peptide to DNA and then amplifying the DNA.

More recently, approaches have been developed that allow the encoding of polypeptides and other biochemical polymers. An example of this approach is disclosed in US 5,723,598, which pertains to the identification of a biochemical polymer that participates in a preselected binding interaction with a target to form a binding reaction complex. The prior art method encompasses the generation of a library of bifunctional molecules. One part of the bifunctional molecule is the biochemical polymer and the other part is an identifier oligonucleotide comprising a sequence of nucleotides which encodes and identifies the biochemical polymer. Following the generation of the library of the bifunctional molecules, a partitioning with respect to affinity towards the target is conducted and the identifier oligonucleotide part of the bi-

functional molecule is amplified by means of PCR. Eventually, the PCR amplicons are sequenced and decoded for identification of the biochemical polymer. This approach does not, however, allow one-pot amplification of the library members. Thus the flow of information from the identifier sequence to the biochemical polymer is restrained.

Halpin and Harbury have in WO 00/23458 suggested an improvement to the approach stipulated immediately above, wherein the molecules formed are not only identified but also directed by the nucleic acid tag. The approach is based on the traditional split-and-combine strategy for synthesis of combinatorial libraries comprising two or more synthetic steps. Plurality nucleic acid templates are used, each having at one end a chemical reactive site and dispersed throughout the strand a plurality of codons regions, each of said codon regions in turn specifying different codons. Separately, each of the strands, identified by a first codon region, is reacted at the chemical reaction sites with specific selected reagents. Subsequently, all the strands are pooled and subjected to a second partitioning based on a second codon region. The split-and-combine method is conducted an appropriate number of times to produce a library of typically between 10^3 and 10^6 different compounds. The split-and-combine method is cumbersome and generates only a relatively small library.

The various known methods for production of libraries as well as novel not yet public methods of the present applicant require building blocks comprising a complementing element able to recognize a coding element of a template. The present invention aims at providing such building blocks. In one aspect, the present invention relates to building blocks capable of being incorporated by a polymerase or reverse transcriptase. In another aspect, the present invention relates to building blocks capable of being incorporated in the absence of an enzyme. The building block comprises, apart from the complementing element, a linker and a functional entity. The functional entity of the compounds of the present invention may comprise an amino acid precursor. When a plurality of the building blocks are incorporated into a complementing template the functional entities are able to be linked to each other, thus forming a templated molecule, the synthesis of which is directed by the coding elements of the template. The characteristic alkynylene moiety of the linkers of the present invention makes it possible to display the functional entity in the major groove of a double stranded molecule. When two or more functional entities are displayed simultaneously in the major groove reactive groups of the functional enti-

simultaneously in the major groove reactive groups of the functional entities may react, either directly or via a suitable bridging molecule, to form a linkage between the functional entities. Thus, upon proper incorporation of a plurality of the compounds of the invention it is possible to form a templated molecule by linking each of the functional entities. The linkers may optionally be cleaved simultaneously with or after the formation of the templated molecule. Preferably at least one linker remains uncleaved to attach the templated molecule to the template which templated the synthesis thereof or a complementing template. A library of different complexes of template (or complementing template) and templated molecule may be subjected to various screening methods, such as affinity screening, known to the person skilled in the art to identify one or more templated molecule with the desired effect.

The compounds of the present invention may be used for the production of natural α-peptides. However, recently a strong interest has been observed in academic societies for peptides other than α-peptides, such as β-peptides, γ-peptides, and δ-peptides. In one aspect of the invention it is contemplated to provide building blocks for the formation of molecules based on such artificial peptides.

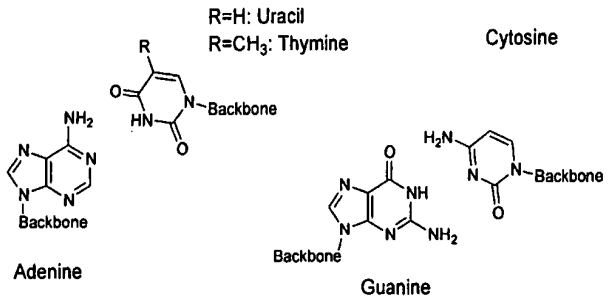
Detailed Description of the Invention

Building blocks consist apart from a linker and a functional entity of one or more nucleoside analogues i.e. pairs of nucleobases and backbone units, forming the complementing entity and may as such be considered a nucleoside derivative. The nucleobase may be of natural or of synthetic origin but all shares the common feature of being able to selectively recognize one other nucleobase. Examples of such base pairs are shown in chart 1

Natural Base Pairs



Synthetic Base Pairs

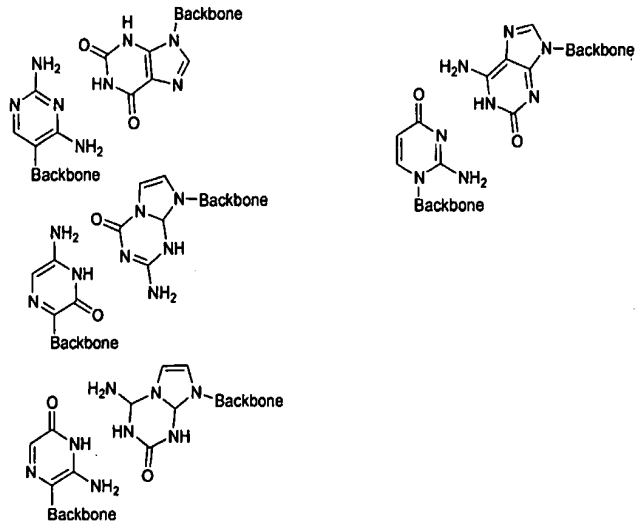


Chart 1 Natural and Synthetic nucleobases.

Also, modifications to both natural- and synthetic nucleobases is possible without obliteration of the mutual recognition properties, e.g. replacing the N-7 atom of adenine or guanidine with a carbon atom affords 7-deaza adenine and 7-deaza guanine

respectively (Chart 2) that still recognises natural thymine or uracil and cytosine, respectively. Further the introduction of substituents at certain positions on the complementing entity is also possible.

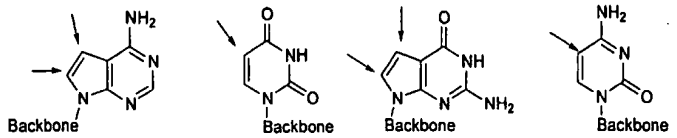

Chart 2. 7-deaza-adenine, uracil, 7-deaza-guanidine and cytosine. Arrows indicate preferred sites of substitution on the nucleobase of the complementing entity that direct the functional entity into the major groove of the nascent oligomer complex.

The backbone units of the building blocks may contain a set of reactive groups that enables enzymatic or chemical oligomerisation of the building blocks. Examples of backbone unit structures are given in chart 3

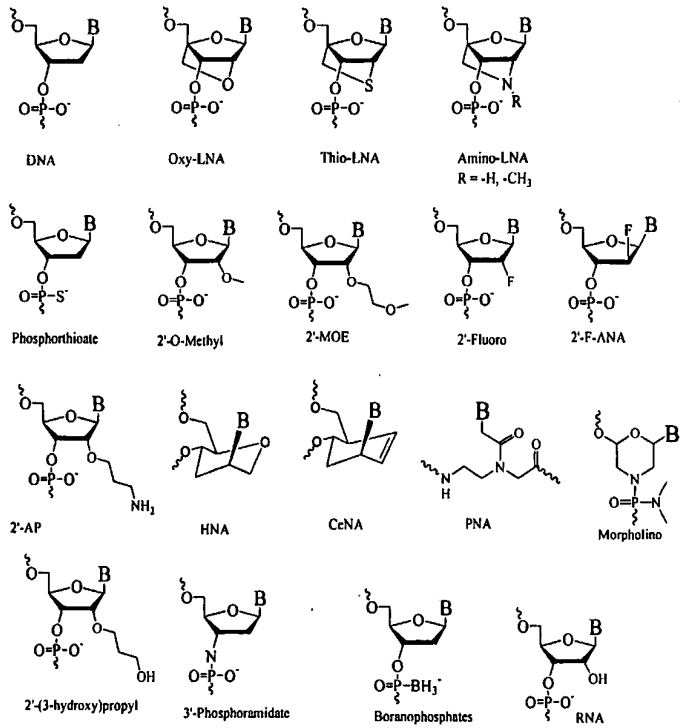

Chart 3 Backbone units used and building blocks. B designates the nucleobase and wavy bonds show points of oligomerisation.

Building blocks may be oligomerised using enzymatic or chemical methods. (Schmidt; **1997**; *Nucleic Acids Research*; 4792-4796,Inoue; **1984**; *Journal of Molecular Biology*; 669-676,Schmidt; **1997**; *Nucleic Acids Research*; 4797-4802) Enzymatic incorporation is typically based on the use of 5'-O-triphosphate building blocks with a ribose derived backbone unit. Chemical incorporation of building blocks with a ribose derived backbone unit relies on the use of an activated phosphate ester e.g. a phoshporimidate. (Zhao; **1998**; *J. Org. Chem.*; 7568-7572) For peptide backbone units, peptide coupling reagents are employed.

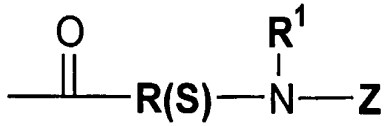
As shown in chart 3 several modifications of the natural DNA- and RNA backbone is possible, particularly the 2-position of the ribose entity is well suited for functional entity linkage.

The linker is based on a rigid alkynylene spacer that positions the functional entity away from the back bone of the oligomer complex: —X—R^2-C≡C—

X is a hetero atom selected from the group O, S, Se or a group NR^4, wherein R^4 is hydrogen or an optionally substituted linear or branched C_{1-6} alkyl or C_{2-6} alkenyl.

R^2 is selected from the group consisting of C_{1-6} alkylen, C_{2-6} alkylenylen, C_{2-6} alkynylen, C_{3-8} cycloalkylen, heterocycloalkylen, $-CH_2-O-$, arylen or heteroarylen, wherein each of the groups R^2 are substituted with 0-3 R^8 groups independently selected from =O, =S, -F, -Cl, -Br, -I, $-OCH_3$, $-NO_2$ or C_{1-6} alkyl

The functional entity is an aminoacid derivative:



Wherein:

R(S) is a C_{1-4} alkylen, C_{3-10} cycloalkylen, aryl, heterocycloalkyl or heteroaryl substituted by n sidechains **S**, wherein n is an integer of 0 to 4

R^6 and R^7 are independently selected from H, C_{1-6} linear alkyl, C_{1-6} branched alkyl, C_{1-6} cycloalkyl, aryl, heteroaryl, aralkyl, or hetero aralkyl.

S is C_{1-6} linear alkyl, C_{3-6} branched alkyl, C_{3-6} cycloalkyl, aryl, heteroaryl, aralkyl, hetero aralkyl substituted with 0-3 R^5 where R^5 is independently selected from =O, Cl, Br, -CN, $-OR^6$, $-SR^6$, $-NR^6R^7$, $-COOR^6$, $-CONR^6R^7$, $-SO_2NR^6R^7$.

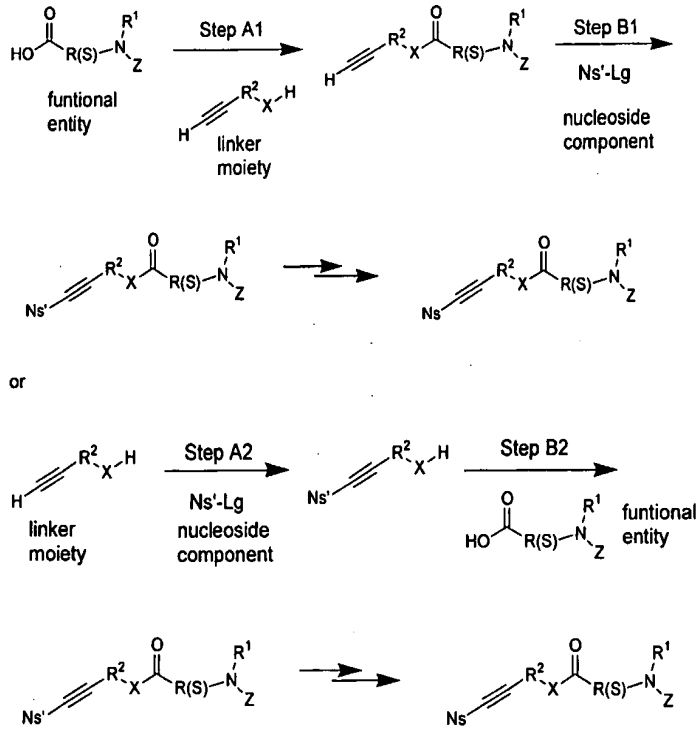
General Synthesis Procedures

The compounds of the invention are generally prepared by two different methods.



Ns' is a precursor of **Ns**, e.g. a 3'-O-5'-O-protected nucleoside.

Lg is a leaving group suitable for Sonogashira couplings exemplified by but not limited to Br and I.

Step A1

The amino acid derivative (functional entity) (10.37 mmol) is dissolved in a solvent exemplified by but not limited to dichloromethane, 1,2-dichloroethane, 1,2-dichloropropane, tetrahydrofuran, dimethylformamid or a mixture hereof and added a peptide coupling reagent (12.44 mmol, 1.2 eq) exemplified by but not limited to EDC, DCC, DIC, HATU, HBTU, PyBoP or PyBroP optionally in the presence of a peptide coupling enhancer like HOBt, HOAt, or NHS at a temperature of -20-100 °C preferably 0-50 °C. To this mixture, the linker moiety (15.55 mmol, 1.5 equiv) is added optionally in the presence of DMAP (1.04 mmol, 0.1 eq) and the reaction is

left 2-16 h. Upon evaporation of volatiles, the residue is taken up in dichloromethan and washed with HCl (aq, 0.1 M); $NaHCO_3$ (aq, sat); and water. Removal of dichloromethan affords the crude product which is further purified by chromatography if necessary.

Step B1

A solution of the nucleoside component (0.34 mmol) in a solvent like dimethylformamid, dimethylsulfoxid, toluene, tetrahydrofuran, water, ethanol, methanol or a mixture herof is added a terminal alkyne (the linker moiety-funtional entity) (0.69 mmol, 2 eq) and a base like DIEA (0.25 mL) and is purged with Ar for 5 min. Tetrakis triphenylphosphine palladium (0.03 mmol, 0.1 eq) and CuI (0.07 mmol, 0.2 eq) is added and the reaction is run at 20-100 °C, preferably at 20-50 °C, and kept there for 20 h. Evaporation of volatiles followed by chromatography affords the desired modified nucleoside.

Step A2

A solution of the complementing element precursor (0.34 mmol) in a solvent like dimethylformamid, dimethylsulfoxid, toluene, tetrahydrofuran, water, ethanol, methanol or a mixture herof is added a terminal alkyne (the linker moiety) (0.69 mmol, 2 eq) and a base like DIEA (0.25 mL) and is purged with Ar for 5 min. Tetrakis triphenylphosphine palladium (0.03 mmol, 0.1 eq) and CuI (0.07 mmol, 0.2 eq) is added and the reaction is run at 20-100 °C, preferably at 20-50 °C, and kept there for 20 h. Evaporation of volatiles followed by chromatography affords the desired modified nucleoside.

Depending on the nature of Ns' several steps known from literature may be required to convert Ns' into Ns e.g. Protective group removal (Greene; **1999**;;) or conversion of 5'OH groups of nucleosides into 5'O-triphosphates or phosphorimidazolides.(Zhao; **1998**; *J. Org. Chem.*; 7568-7572)

Nucleoside analogues with phosphate linkages in the backbone may be combined with wild type nucleotides to form di-, tri- or oligomeric buildingblocks. Likewise, nucleoside analogues having a PNA backbone unit may be combined with PNA monomers to form di-, tri- or oligomeric building blocks.

Step B2

The amino acid derivative (functional entity) (10.37 mmol) is dissolved in a solvent exemplified by but not limited to dichloromethane, 1,2-dichloroethane, 1,2-dichloropropane, tetrahydrofuran, dimethylformamid or a mixture hereof and added a peptide coupling reagent (12.44 mmol, 1.2 eq) exemplified by but not limited to EDC, DCC, DIC, HATU, HBTU, PyBoP or PyBroP optionally in the presence of a peptide coupling enhancer like HOBt, HOAt, or NHS at a temperature of -20-100 °C preferably 0-50 °C. To this mixture, the linker-nucleoside component (15.55 mmol, 1.5 equiv) obtained in step A2 is added optionally in the presence of DMAP (1.04 mmol, 0.1 eq) and the reaction is left 2-16 h. Upon evaporation of volatiles, the residue is taken up in dichloromethan and washed with HCl (aq, 0.1 M); $NaHCO_3$ (aq, sat); and water. Removal of dichloromethan affords the crude product which may be further purified by chromatography if necessary.

Depending on the nature of Ns' several steps known from literature may be required to convert Ns' into Ns e.g. protective group removal, conversion of 5'-OH groups of ribose derived backbone units into 5'-O-triphosphates or phosphorimidazolides. (Zhao; **1998**; *J. Org. Chem.*; 7568-7572). For peptide derived backbone units other types of modifications are required. (Hyrup; **1996**; *Bioorganic & medicinal chemistry*; 5-23)

Nucleoside analogues carrying a ribose derived backbone unit may be combined with wild type nucleotides to form di-, tri- or oligo-nucleotid building blocks. Likewise, nucleoside analogues having a peptide backbone unit may be combined with PNA monomers to form di-, tri or oligo peptidic building blocks.

COMPOUND V

Removal of *N-Boc* protection group.

Following phosphorylation, 50 µl of the phosphorylation reaction mixture is adjusted to pH = 1 using HCl and incubated at room temperature for 30 minutes. The mixture is adjusted to pH 5.5 using equimolar NaOH and Na-acetate (pH 5.5) before purification on TLC.

Purification of nucleotide derivatives using thin-layer chromatography (TLC)

From the crude mixture, 20 samples of 2 µl were spotted on kieselgel 60 F_{254} TLC (Merck). Organic solvents and non-phosphorylated nucleosides were separated from the nucleotides derivatives using 100% methanol as running solution. Subsequently, the TLC plate is air-dried and the nucleotide-derivative identified by UV-shadowing. Kiesel containing the nucleotide-derivative was isolated and extracted twice using 10 mM Na-acetate (pH = 5.5) as solvent. Kieselgel was removed by centrifugation and the supernatant was dried *in vacuo*. The nucleotide derivative was resuspended in 50-100 µl H_2O to a final concentration of 1-3 mM. The concentration of each nucleotide derivative was evaluated by UV-absorption prior to use in polymerase extension reactions.

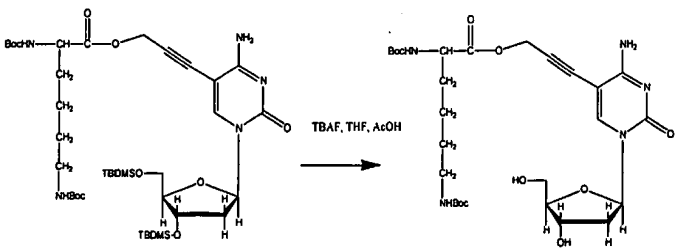
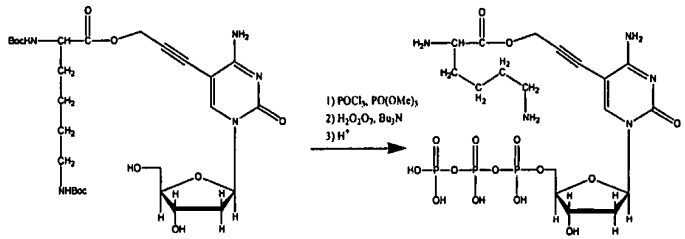
Example 44: Preparation of 5-(di-Boc-Lysin-propargyl ester)-2'-deoxycytidine (compound 10e) $C_{28}H_{43}IN_5O_{10}$ Mw 609.67



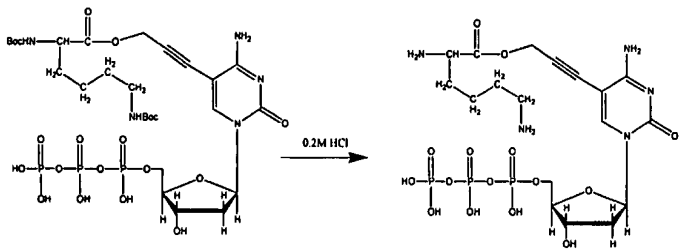
Compound 10d (0.0246 g, 0.029 mmol) was dissolved in THF (1 ml) and successively added acetic acid (0.0165 ml, 0.288 mmol) and tetra n-butyl ammonium fluoride tri-hydrate (0.0454 g, 0.144 mmol). The reaction mixture was stirred for 18 h at room temperature and afterwards evaporated. Re-dissolved in dichloromethane and purified on silica (1 x 18 cm). Dichloromethane/MeOH 8:2. Fractions which gave UV absorbance on TLC were pooled and evaporated giving 10e (0.0128 g) as a colourless oil.

Example 45: Preparation of 5-(Lysin-propargyl ester)-5'-triphosphate-2'-deoxycytidine $C_{18}H_{30}N_5O_{15}P_3$ Mw 649.38



Compound 10e (0.0128 g, 0.021 mmol) was dissolved in trimethylphosphate (0.150 ml) and cooled to 0 °C. Phosphoroxychloride in trimethylphosphate (1M, 0.0246 ml) was added slowly in order not to raise the temperature. Stirring was continued for 2 h at 0 °C and the temperature was allowed to rise to ambient. Pyrophosphate in DMF (0.5 M, 0.1025 ml, 0.051 mmol) and tri-n-butyl amine in DMF (1M, 0.0122 ml, 0.051 mmol) were added simultaneous. Stirring was continued for 15 minutes at room temperature and TEAB(triethyl ammonium bicarbonate, 1M, pH = 7.3, 0.50ml) was added. Stirring was continued for 3 h then evaporated.

Example 46: Preparation of compound X



The crude material was treated with aqueous hydrochloric acid (0.2 M, 1 ml) for 15 minutes at 30 °C. Compound X was obtained by HPLC C_{18} 10 mM TEAA (triethylammonium acetate) in water to 10 mM TEAA 20% water in acetonitrile. Appropriate fractions were desalted using gelfiltration (pharmacia G-10, 0.7 ml)

Example 47: Polymerase incorporation of different nucleotide derivatives.

Different extension primers were 5'-labeled with ^{32}P using T4 polynucleotide kinase using standard protocol (Promega, cat# 4103). These extension primers was annealed to a template primer using 0.1 and 3 pmol respectively in an extension buffer (20 mM Hepes, 40 mM KCl, 8 mM $MgCl_2$, pH 7.4, 10 mM DTT) by heating to 80 °C for 2 min. and then slowly cooling to about 20 °C. The wild type nucleotide or nucleotide derivatives was then added (about 100 µM) and incorporated using 5 units AMV Reverse Transcriptase (Promega, part# 9PIM510) at 30 °C for 1 hour. The samples were mixed with formamide dye and run on a 10% urea polyacrylamide gel electrophoresis. The gel was developed using autoradiography (Kodak, BioMax film). The incorporation can be identified by the different mobility shift for the nucleotide derivatives compared to the wild type nucleotide. Figure 1 shows incorporation of various nucleotide derivates. In lane 1-5 the extension primer 5'-GCT ACT GGC ATC GGT-3' was used together with the template primer 5'-GCT GTC TGC AAG TGA TAA CCG ATG CCA GTA GC-3', in lane 6-11 extension primer 5'-GCT ACT GGC ATC GGT-3' was used together with the template primer 5'-GCT GTC TGC AAG TGA TGA CCG ATG CCA GTA GC-3', and in lane 12-15 the extension primer 5'-GCT ACT GGC ATC GGT-3' was used together with the template primer 5'-GCT GTC TGC AAG TGA CGT AAC CGA TGC CAG TAG C-3'. INTERNATIONAL SEARCH REPORT

International application No.
PCT/DK 02/00420

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. ☒ Claims Nos.: -
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
see FURTHER INFORMATION sheet PCT/ISA/210

3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.

2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.

3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:

4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

☐ The additional search fees were accompanied by the applicant's protest.

☐ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

Continuation of Box I.2

Present claims 1-41 relate to an extremely large number of possible compounds. Support within the meaning of Article 6 PCT and/or disclosure within the meaning of Article 5 PCT is to be found, however, for only a very small proportion of the compounds claimed. In the present case, the claims so lack support, and the application so lacks disclosure, that a meaningful search over the whole of the claimed scope is impossible. Consequently, the search has been carried out for those parts of the claims which appear to be supported and disclosed, namely those parts relating to the compounds of the general formula in claim 1, wherein:
(1) the alkynylen linker is connected to the nucleobase of a nucleoside analogue in the 7 position of the bicyclic purine nucleobases and the 5 position of the monocyclic pyrimidine bases (as defined in claim 3),
and
(2) R(S) is a C1-4 alkylene,
and
(3) the backbone unit-type is DNA or RNA.

The applicant's attention is drawn to the fact that claims, or parts of claims, relating to inventions in respect of which no international search report has been established need not be the subject of an international preliminary examination (Rule 66.1(e) PCT). The applicant is advised that the EPO policy when acting as an International Preliminary Examining Authority is normally not to carry out a preliminary examination on matter which has not been searched. This is the case irrespective of whether or not the claims are amended following receipt of the search report or during any Chapter II procedure.
